Mission Statement

Massively parallel accelerators, primarily GPUs, are now widespread, offering tremendous compute power at a low cost. Tasks such as media processing, simulation, medical imaging and emotion tracking can be accelerated to beat CPU performance, sometimes by orders of magnitude, and performance is gained in both energy efficiency and execution speed, allowing intensive media processing software to run in low-power consumer devices. However, low-level programming of heterogeneous accelerators is notoriously difficult.

The aim of CARP is to design techniques and tools for correct and efficient accelerator programming:

- Novel and attractive methods for constructing system-independent accelerator programs
- Advanced code generation techniques to produce highly optimised system-specific code from system-independent programs
- Scalable static techniques for analysing accelerator software both qualitatively and quantitatively

These methods will provide a unified development flow for accelerated software, reducing cost and time-to-market quotas, increasing energy efficiency and improving reliability.

Technical Approach

As shown in the figure, CARP is centred around the design of a novel language, PENCIL (Platform Neutral Compute Intermediate Language), for productive accelerator programming. PENCIL is supported by advanced compilation tools based on the polyhedral model, which generate low-level code targeting the widely adopted OpenCL industry standard. Portable performance will be achieved through profile-based auto-tuning, enabling compiled code to run efficiently across a range of accelerator platforms. Compiler optimisations will be geared towards reducing execution time and increasing energy efficiency.

To aid design of portably correct accelerator software, the CARP approach involves formal analysis at both the PENCIL and OpenCL levels using deductive verification methods, including automated Hoare logic and separation logic. The aim will be to automatically discover bugs in accelerator software, establish correctness for critical portions of code, e.g. libraries, and aid program understanding.
Selected results so far (see www.carpproject.eu for the latest news and publications)

- **PENCIL language definition:** The first draft of the PENCIL language is complete, allowing construction of compilation tools. For early details of PENCIL see our paper at WOLFHPC’12.
- **DSL → PENCIL → OpenCL compilation flow:** We have a prototype tool chain for compiling programs in VOBLA, a linear algebra DSL, to PENCIL and then to OpenCL for acceleration on GPU architectures.
- **GPUVerify tool:** GPUVerify is a highly automatic tool for source-level analysis of GPU kernels written in OpenCL and CUDA. See our OOPSLA’12 paper for details, and check out GPUVerify on YouTube.
- **Techniques for software cost analysis:** We have designed methods for estimating the worst-case execution time of GPU kernels, and for formally establishing quantitative properties of probabilistic programs. See papers at ECRTS and QEST.

Demonstration and Use

The CARP technology will be demonstrated via the implementation of real-time emotion tracking algorithms by Realeyes. Currently, Realeyes perform post-processing to extract and analyse gaze information from video streams. The CARP compilation techniques will enable this to be performed in real-time, across multiple platforms including mobile devices, in an energy-efficient manner. The verification technology will provide maximum confidence in the reliability and probity of this software. The CARP verification techniques will also be demonstrated by Rightware and ARM, through analysis of their OpenCL benchmark and demo suites. ARM will use the state-of-the-art program analysis techniques developed during CARP to enhance their software development tool-chains. In addition, selected software tools arising from CARP will be made publicly available, enabling general adoption.

Scientific, Economic and Societal Impact

ARM’s involvement as world leaders in processor design, together with input from three high-technology European SMEs, will ensure rapid commercialisation of the project outputs. This will enhance Europe’s competitiveness in the emerging global accelerator software market, ultimately leading to the creation of high-profile technology jobs within EU member states. It is expected that, as a result of the project, Realeyes will significantly increase their share of the estimated 800M€ market in emotion tracking and emotion measurement for commercial research, and break into new markets via real-time applications. Rightware will also be able to enhance their OpenCL benchmark suites, and Monoidics will market next-generation program analysis tools for accelerators.

These benefits will be facilitated by collaboration with four of Europe’s leading academic research centres: Imperial College London, École Normale Supérieure, RWTH Aachen University and University of Twente, whose research efforts will lead to exciting scientific discoveries and high-impact publications, and who will themselves benefit enormously from such an intensive collaboration with industry.

For society at large, CARP will result in increased reliability and capability of consumer software, especially running in mobile devices, as well improvements in critical application domains where accelerators are becoming prominent, such as real-time medical imaging.

**Key Features**
- Order-of-magnitude improvement in productivity of accelerator software development
- Performance of compiled code competitive with that of hand-optimised code on multiple platforms
- Lower energy consumption by accelerated software, leading to greener systems, improved mobile battery life and wider availability on economical platforms
